Distortion Energy Theory:

The distortion energy theory says that failure occurs due to distortion of a part, not due to volumetric changes in the part (distortion causes shearing, but volumetric changes due not).

As examples:

Rocks below the earths surface. Pressure exerted on them is essentially uniform and well beyond their compressive ultimate strengths, yet they are able to withstand the pressure without fracture. The explanation for their survival is that because their shape is not distorted, there is no shearing, therefore no failure.

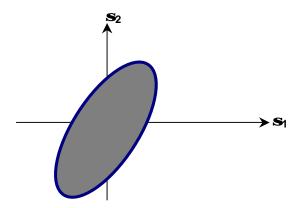

Failure will occur if

$$\mathbf{s}' = \sqrt{\mathbf{s}_1^2 + \mathbf{s}_2^2 + \mathbf{s}_3^2 - \mathbf{s}_1 \mathbf{s}_2 - \mathbf{s}_2 \mathbf{s}_3 - \mathbf{s}_1 \mathbf{s}_3} \ge \mathbf{S}_y$$

In terms of applied stresses

$$\mathbf{s}' = \sqrt{\frac{\left(\mathbf{s}_{x} - \mathbf{s}_{y}\right)^{2} + \left(\mathbf{s}_{y} - \mathbf{s}_{z}\right)^{2} + \left(\mathbf{s}_{z} - \mathbf{s}_{xy}\right)^{2} + 6\left(\mathbf{t}_{xy}^{2} + \mathbf{t}_{yz}^{2} + \mathbf{t}_{zx}^{2}\right)}{2}}$$

 σ ' is called the Von Mises effective stress.

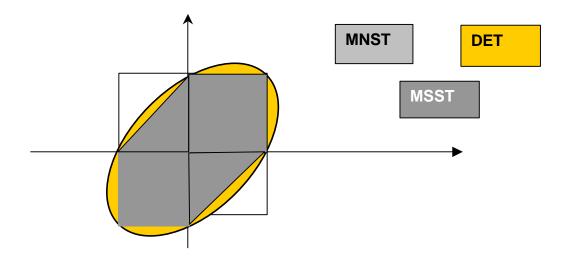

For the case of pure shear, i.e., $\sigma 1 = \tau = -\sigma 3$, $\sigma 2 = 0$

$$S^{2}_{y} = \mathbf{s}^{2}_{1} - \mathbf{s}_{1}\mathbf{s}_{3} + \mathbf{s}_{3}^{2} = 3\mathbf{s}^{2}_{1} = 3\mathbf{t}^{2}_{\text{max}}$$

 $\mathbf{s}_{1} = \frac{S_{y}}{\sqrt{3}} = 0.577S_{y} = \mathbf{t}_{\text{max}}$

Shear yield strength, Ssy = 0.577 Sy

Distortion Energy Theory is less conservative than Maximum Shear Strength Theory, but more conservative than the Maximum Normal Stress Theory

Determine whether or failure is predicted with the Distortion Energy Theory for the shaft loaded as shown
