# **Aeroelastic Loads and Response of Wind Turbine Blades**

**The primary objective of this research is to develop a better understanding of the Aeroelastic loads and responses of healthy and damaged wind turbine blades in varying wind conditions, (i.e. smooth flow, turbulent flow, gusty winds, and yaw misalignment).**

**OBJECTIVE**

# AEROELASTICS

# **AEROELASTICS**

**The study of the effect of  
aerodynamic forces on  
elastic bodies**

# FLUTTER

**Known as a self-excited response, flutter is characterized by the interplay between aerodynamic, elastic, and inertial forces. Flutter is sometimes known as dynamic aeroelastic instability. Particularly dangerous when small disturbances (essentially incidental) induce violent oscillations!**

## FLUTTER SPEED

**Above a certain wind speed the kinetic energy of the structure will no longer be dissipated and it will become dynamically unstable. This wind speed is known as the flutter speed.**

# Are Wind Turbine Blades Susceptible to Flutter?

**Short Answer: No**

**But...**

**The flutter speed of a typical (1.5 MW) wind turbine blade is about 2x the operating wind speed and the flutter speed decreases as the blade gets longer!**

# Then why is this research important?

**Wind turbine blades deform when operating and when parked. The hope is to use these deformations as a means to identify damage in the blade. But, in order to use it we must first understand the loads and the inherent response of the blade when it is deforming. This should allow us to identify areas where the stress is higher than it should be, indicating damage.**

## **But how?**

**Stress increases around a hole in a plate**

**The stress concentration factor in this region is 3. Meaning that the stress seen in this area is three times the load being applied to the plate!**

$$\text{Stress Concentration Factor} = \frac{\text{Maximum Stress in Region}}{\text{Load applied}}$$

# Stress around a hole in a plate

# Flutter Derivatives

$$L_{se} = \frac{1}{2} \rho U^2 B \left[ KH_1^*(K) \frac{\dot{h}}{U} + KH_2^*(K) \frac{B\dot{\alpha}}{U} + K^2 H_3^*(K) \alpha + K^2 H_4^*(K) \frac{h}{B} \right]$$

$$M_{se} = \frac{1}{2} \rho U^2 B^2 \left[ KA_1^*(K) \frac{\dot{h}}{U} + KA_2^*(K) \frac{B\dot{\alpha}}{U} + K^2 A_3^*(K) \alpha + K^2 A_4^*(K) \frac{h}{B} \right]$$

**Each flutter derivative tells us something different about the response. For example,  $H_1^*$  is aerodynamic damping in the vertical and  $A_2^*$  is aerodynamic damping in torsion.**

**These are the equations for the 2 degrees of freedom case. When considering all 3 DOFs there are 18 flutter derivatives.**

$$H_1^* = -\frac{1}{K} \left( \frac{dC_L}{d\alpha} + C_D \right)$$

$$A_1^* = \frac{1}{K} \frac{dC_M}{d\alpha}$$

$$H_3^* = -\frac{1}{K^2} \frac{dC_L}{d\alpha}$$

$$A_3^* = \frac{1}{K^2} \frac{dC_M}{d\alpha}$$

**Reduced Frequency**

$$K = \frac{2\pi}{RV}$$

# Quasi-Steady Flutter Derivatives

**Reduced Velocity**

$$RV = \frac{U}{fB}$$

# How?

**Section Model Test**

**2 DOF Forced Vibration**

**Measure Force and Torque  
to get displacement**

**Pressure Distribution to  
calculate lift and moment**

**Extract Rational Functions**

**Calculate Flutter Derivatives**

# Task 1: Extracting Flutter Derivatives of the S830 Airfoil
